ABSTRACT
This research wants to examine how the management of the creation of works of art made from organic waste (wood and marine biota) in Jaring Halus Village, North Sumatra. The method used in this study was the method of creation with an experimental model by utilizing waste as a model for creating works of art. The research was conducted in Jaring Halus Village, Langkat, North Sumatra. The stages in this research begin with identifying internal and external potentials. The internal potential is the location and organic waste such as waste wood and marine biota and the like. Furthermore, the external potential was the community's ability to explore the aesthetic power of waste to become an expression of works of art; in this case, presentations and design workshops are held through design simulations and references. The next step was selecting the quality of the waste wood, which includes elements of shape, structure, texture, and size. Based on the results of the research conducted, it can be concluded that some of the research findings are as follows: 1) the steps taken include: Planning, Mapping of waste locations, Mapping types of waste in categories, Understanding design as a material for creating works of art, Process of assembling forms works of art, the process of refining, the Process of presenting works of art. 2) In managing the creation of works of art by utilizing organic waste (wood and marine biota), we have produced several new prototypes of works of art made from organic waste. 3) Using creative methods based on adaptive and connotative patterns greatly encourages the creation of more significant and productive works of art.

INTRODUCTION
Waste is unused waste material which have a negative impact on society if not managed properly. Industrial and household (domestic) waste water if not managed properly will have a negative impact on health. Waste is a substance produced from a production process, both industrial and domestic (household). Waste can be in the form of garbage, toilet water, and waste water from various other domestic activities. Waste must be managed properly so as not to have a negative impact on the environment. According to Marliani (2014:124), increasing the volume of waste requires serious handling of waste management. Waste management that does not use waste management methods and techniques environmentally friendly besides being able to have a negative impact on health will also greatly interfere with the preservation of environmental functions both residential, forests, fields, rivers and oceans. One form of waste is household waste stairs in the form of inorganic waste. This waste is very dangerous for the environment and health because this inorganic waste is made from natural sources that cannot be refurbished and contain chemicals, but its existence is
only glimpsed next door eye. there needs to be good waste management by making it a work that can be produced. Management functions to plan, implement, and monitor evaluation (Tobing, 2018:58).

This study wants to examine how the management of the creation of works of art made from organic waste (wood and marine biota) in Jaring Halus Village, North Sumatra. Jaring Halus Village is topographically located in the province of North Sumatra. In this village, much organic waste is left unattended. according to Fuad et al (2017:39), organic waste is a fairly serious environmental problem that is still being faced by the community. This situation can be used as a source of media for creating creative works that have economic value. Many creative things can be done if we are able to explore a large amount of organic waste, such as wood or marine biota, which is neglected and cannot be utilized by the community. Based on the results of observations and discussions conducted by the research team, it is important to take action to utilize and manage these wastes as a source of media in increasing the productivity of works of art for the perpetrators.

Based on the results of observations and discussions conducted by the research team, art academics, and local artisans, found several facts and data that productivity in doing works of art, especially fine arts, has decreased in terms of creativity. This is caused by several things, including the lack of utilization of easily available sources of art media such as organic waste and many more. Declining public interest in appreciating works of art decreases the productivity of artists in creating works of art by utilizing media sources that are easy to find. Thus it is highly recommended to provide a way out of how artists or artisans can remain creative and exist and increase the productivity of works of art that have economic value and can be appreciated by the wider community.

Innovative works of art will be born from creative artists, fine art products are the interaction of all aesthetic experiences that are formed from visual experiences and are integrated from the taste. How can we do the best management of the existing waste to increase artists' productivity in creating art. Based on the background described above, this research focuses on examining two things that are considered essential, namely (1) How to manage organic waste management as an effort to increase the productivity of works of art. The objectives of this study are (1) to be able to manage organic waste management as an increase in the productivity of works of art, especially in North Sumatra.

METHOD

The method used in this study was the method of creation with an experimental model by utilizing waste as a model for creating works of art in the form of souvenirs. The research was conducted in Jaring Halus Village, Langkat, North Sumatra, with a population of 10 artisans as a sample (random sampling). The stages in this research began with identifying internal and external potentials. The internal potential was the presence of waste wood and other organic wastes such as marine biota waste, shellfish shells, crab shells, shrimp shells and its kind. Furthermore, the external potential was the community's ability to explore the aesthetic power of wood and other organic waste to become an expression of works of art; in this case, presentations and design workshops are held through design simulations and references. The next step was selecting the waste wood's quality, including elements of shape, structure, texture and size. The waste were then cleaned by conventional rinsings, such as rinsing with washing detergent and chemical elements, especially for cleaning marine biota waste, which uses liquid chlorine as a bleach.
Osberth Sinaga et.al, Local Waste Management As An Effort Increasing the Productivity...
generally found on websites so that they can stimulate creative ideas and ideas. Before arriving at a copyright on the waste wood media, a simulation must be conducted by compiling each element of the existing waste wood according to their needs. Compilation simulations are carried out in an instant and temporary or flexible manner so that it was possible to develop creative ideas into other forms. The concept of creative ideas was not bound by normative conventions but is relative, connotative, symbolic and expressive. Concepts and approaches like this allow the birth of creative works with their idioms and uniqueness, which then become a visual sensation as well as an attraction to the work. In accordance with their form, these works can lead to the form of souvenir works and works of pure, abstraction and contemporary art.

The fifth step was assembling consisting of two types of motifs, namely realist and abstract motifs. Assembling on realist motifs was to determine the primary elements of wooden forms, such as animal shapes or other creatures, then it was done by completing other elements, such as fish fins, fish teeth and many more. The assembly process was carried out using a good gluing model with wooden pens, nails or adhesive glue. There were three types of glue used, namely faster or instant glue (Shetan brand). This type of glue has a very fast adhesive reaction in just seconds and can be used on all types of media. The next glue was in the medium glue category, such as the goat glue brand. Goat glue has a balanced adhesiveness, that was, on both sides of the elements to be joined, so both surfaces are equally glued first, and it took a relatively short time between 1 - to 15 minutes. This glue was used to glue surfaces that are wider than 2 cm. The next glue is the massive category of slow (Low) glue, namely PVC glue, known as Rakol glue or the Fox brand; this glue was white-like paste that was very suitable for wood or paper glue. This type of massive glue took a long time to dry, so to secure each glued joint, it must be protected by tying the objects being glued together until the glue was completely dry. Under normal temperature conditions, such as indoors, this type of PVC glue requires a drying time of up to 6 hours at a glue thickness of 0.3 – 1.0 mm.

The sixth step was the process of refining both the wood surface and each joint. The refining Process requires a high level of patience; the finer the work, the better. The refining stage was to use a polishing tool, either using a grinder or sandpaper or sand paper. For refining that takes a long time, a mini grinder was used, which was a type of flexible hand grinder equipped with a rotating rope, making it easier to rub finely on complex and small surfaces or surfaces. Small grinders used for grinding and refining small and complex surfaces have a polishing rotor with a diameter of between 3 and 20 mm in either a cylindrical or spherical, or oval shape. For refining on wide areas and rough surfaces, sandpaper is used, namely sandpaper with a surface size of 0 - 3 as a measure of smoothness and roughness. Sandpaper scrubbing was done by hand repeatedly as desired. After this stage, the next stage was coloring and coating. This stage was done in two ways, namely spraying (brushing) using a clear spray and painting with a brush. Staining of waste wood was not done with impasto paint which was covering but was done with a transparent layer that was adaptive such as impra brand polytur. This type of varnish has characteristic colors of wood such as brown and maroon, ocher in color, as well as the coating using pixative clear from the Pylox brand, which was transparent and water repellent, as well as coating or coating of varnish.

The seventh step was the final stage, namely, presentation or presentation based on the motive of his work. For key chain souvenirs, a metal ring was given as a hanger, and for
works of art, realist and abstract motifs were countered with iron or other metal elements such as wire and bedstal as mini bearings for the product.

The experimental cycle of innovation in the creation of works of art made from waste wood and marine biota waste was as follows:

Replication of the prototype based on the shape and motif of naturally found waste wood. The motifs found in waste wood can be in the form of realist or non-realist motifs. Pattern formation is influenced by the creator's level of sensitivity to the waste wood object.

Forming motifs or patterns with artistic innovation is done by cutting, combining, punching holes, whittling, gouging.

CONCLUSIONS

Based on the description that has been explained, several conclusions can be drawn as follows:

1. Based on the results of the discussion and design carried out by the research team, the steps taken include 1) Planning and preparation of activities. 2) Mapping of waste locations. 3) Mapping of types of waste in categories. 4) Understanding of design was considered appropriate as a material for creating works of art (souvenirs). 5) The process of assembling the form of a work of art. 5) Refining process. 7) The Process of presenting works of art.

2. In managing the creation of works of art by utilizing organic waste (wood and marine biota), we have been able to produce several new prototypes of works of art made from organic waste.

3. Using creative methods based on adaptive and connotative patterns greatly encourages the creation of larger and more productive works of art.
